A Handbook of Statistical Analyses Using $\mathsf{R} - 2\mathrm{nd}$ Edition

Brian S. Everitt and Torsten Hothorn

CHAPTER 12

Analysing Longitudinal Data I: Computerised Delivery of Cognitive Behavioural Therapy – Beat the Blues

12.1 Introduction

12.2 Analysing Longitudinal Data

12.3 Analysis Using R

We shall fit both random intercept and random intercept and slope models to the data including the baseline BDI values (pre.bdi), treatment group, drug and length as fixed effect covariates. Linear mixed effects models are fitted in R by using the lmer function contained in the lme4 package (Bates and Sarkar, 2008, Pinheiro and Bates, 2000, Bates, 2005), but an essential first step is to rearrange the data from the 'wide form' in which they appear in the BtheB data frame into the 'long form' in which each separate repeated measurement and associated covariate values appear as a separate row in a data frame. This rearrangement can be made using the following code:

R> subset(BtheB_long, subject %in% c("1", "2", "3"))

	drug	length	treatment	bdi.pre	subject	time	bdi
1.2m	No	>6m	TAU	29	1	2	2
2.2m	Yes	>6m	BtheB	32	2	2	16
3.2m	Yes	<6m	TAU	25	3	2	20
1.3m	No	>6m	TAU	29	1	3	2
2.3m	Yes	>6m	BtheB	32	2	3	24
3.3m	Yes	<6m	TAU	25	3	3	NA
1.5m	No	>6m	TAU	29	1	5	NA
$2.5 \mathrm{m}$	Yes	>6m	BtheB	32	2	5	17
3.5m	Yes	<6m	TAU	25	3	5	NA
1.8m	No	>6m	TAU	29	1	8	NA

```
R> data("BtheB", package = "HSAUR2")
R> layout(matrix(1:2, nrow = 1))
R> ylim <- range(BtheB[,grep("bdi", names(BtheB))],</pre>
                  na.rm = TRUE)
R> tau <- subset(BtheB, treatment == "TAU")[,</pre>
       grep("bdi", names(BtheB))]
   boxplot(tau, main = "Treated as Usual", ylab = "BDI",
           xlab = "Time (in months)", names = c(0, 2, 3, 5, 8),
           ylim = ylim)
+
R> btheb <- subset(BtheB, treatment == "BtheB")[,</pre>
+
       grep("bdi", names(BtheB))]
R> boxplot(btheb, main = "Beat the Blues", ylab = "BDI",
           xlab = "Time (in months)", names = c(0, 2, 3, 5, 8),
+
           ylim = ylim)
```

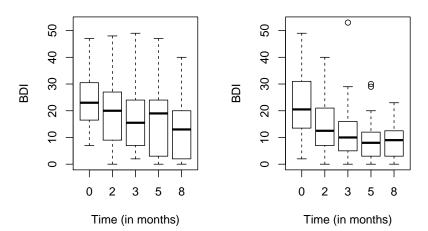

Figure 12.1 Boxplots for the repeated measures by treatment group for the BtheB data.

2.8m	Yes	>6m	BtheB	32	2	8	20
3.8m	Yes	<6m	TAU	2.5	.3	8	NA

The resulting data.frame BtheB_long contains a number of missing values and in applying the lmer function these will be dropped. But notice it is only the missing values that are removed, not participants that have at least one missing value. All the available data is used in the model fitting process. The lmer function is used in a similar way to the lm function met in Chapter 6 with the addition of a random term to identify the source of the repeated

measurements, here subject. We can fit the two models (??) and (??) and test which is most appropriate using

```
R> library("lme4")
R> BtheB_lmer1 <- lmer(bdi ~ bdi.pre + time + treatment + drug +
       length + (1 | subject), data = BtheB_long,
       REML = FALSE, na.action = na.omit)
R> BtheB_lmer2 <- lmer(bdi ~ bdi.pre + time + treatment + drug +</pre>
       length + (time | subject), data = BtheB_long,
       REML = FALSE, na.action = na.omit)
R> anova(BtheB_lmer1, BtheB_lmer2)
Data: BtheB_long
Models:
BtheB_lmer1: bdi ~ bdi.pre + time + treatment + drug + length + (1 | subject)
BtheB_lmer2: bdi ~ bdi.pre + time + treatment + drug + length + (time | subject)
            Df
                  AIC
                        BIC logLik Chisq Chi Df Pr(>Chisq)
BtheB_lmer1 8 1887.5 1916.6 -935.75
BtheB_lmer2 10 1891.0 1927.4 -935.52 0.4542
                                                         0.7969
```

The summary method for lmer objects doesn't print p-values for Gaussian mixed models because the degrees of freedom of the t reference distribution are not obvious. However, one can rely on the asymptotic normal distribution for computing univariate p-values for the fixed effects using the cftest function from package multcomp. The asymptotic p-values are given in Figure 12.3.

We can check the assumptions of the final model fitted to the BtheB data, i.e., the normality of the random effect terms and the residuals, by first using the ranef method to predict the former and the residuals method to calculate the differences between the observed data values and the fitted values, and then using normal probability plots on each. How the random effects are predicted is explained briefly in Section~??. The necessary R code to obtain the effects, residuals and plots is shown with Figure~12.4. There appear to be no large departures from linearity in either plot.
